

P2P Bank

Authors: Max Herich, Lukáš Dvořák

Date of Completion: January 28, 2026

School Name: SPŠE Ječná

Note: This is a school project for subject PV.

Requirements Specification

- The goal is to create a node based on the P2P design pattern. Each node represents a bank where a user can create a bank account, deposit money, or withdraw money.

Application Architecture

- Programming Language: The project is primarily programmed in C#.
- Design Patterns: The Peer-to-Peer, Command, and Factory patterns are utilized.
- Data Storage: Data is stored in a JSON file.

Behavioral Description

- After starting the server, a user can connect to it (e.g., using PuTTY) and work with commands for managing bank accounts and money. These commands are listed and explained in the README file.

Error Handling

- If a user attempts to use a command that the server does not support or enters a command with incorrect syntax, the UnknownCommand is executed. This command alerts the user that something is incorrect.

User Interface

- on url <http://localhost:5000/> is running user interface that is showing all accounts through all banks in the interbank system and showing their number of account, what bank they belong to and their balance on the account.

Reused code

- P2P pattern and Command pattern have been implemented from authors projects from previous years.

Conclusion

- The project has fulfilled the established requirements. An executable P2P server has been created, representing an interbank system. It is possible to connect to it and control it using predefined commands; the system is fully functional.
